In: Nagy ZT, Backeljau T, De Meyer M, Jordaens K (Eds) DNA barcoding: a practical tool for fundamental and applied biodiversity research. ZooKeys 365: 105-126. doi: 10.3897/zookeys. 365.5526

#### Abstract

The taxonomy of stag beetles (Coleoptera: Lucanidae) remains challenging, mainly due to the sexual dimorphism and the strong allometry in males. Such conjecture confounds taxonomic based conservation efforts that are urgently needed due to numerous threats to stag beetle biodiversity. Molecular tools could help solve the problem of identification of the different recognized taxa in the "Lucanus cervus complex" and in some related Palaearctic species. We investigated the potential use of a 670 bp region at the 3 ' end of the mitochondrial cytochrome $c$ oxidase subunit I gene (COI) for barcoding purposes (different from the standard COI barcoding region). Well resolved species and subspecies were $L$. tetraodon, L. cervus akbesianus, L. c. laticornis, as well as the two eastern Asian outgroup taxa L. formosanus and $L$. hermani. Conversely, certain taxa could not be distinguished from each other based on K2P-distances and tree

[^0]topologies: L. c. fabiani / L. (P.) barbarossa, L. c. judaicus / an unknown Lucanus species, L. c. cervus / L. c. turcicus / L. c. pentaphyllus / L. (P.) macrophyllus / L. ibericus. The relative roles of phenotypic plasticity, recurrent hybridisation and incomplete lineage sorting underlying taxonomic and phylogenetic discordances are discussed.

## Keywords

Lucanus spp., Stag beetle, Western Palaearctic, DNA barcoding, COI

## Introduction

Lucanidae Latreille, 1804 is a family of Coleoptera showing in most species pronounced sexual dimorphism and strong external morphological allometry in males. The species of the Holarctic and Oriental distributed genus Lucanus Scopoli, 1763 are renowned for the striking appearance of the males. With their large body size and prominent mandibles, the male stag beetles are very popular among amateur entomologists and as terrarium pets, mainly in Japan. Currently, there are more than 90 Lucanus species described, however, validity of these designations is considered questionable in many cases. Sexual dimorphism and size variation complicate the taxonomy (Didier and Séguy 1953, Clark 1977, Harvey and Gange 2006), as does the lack of informative phenotypic characters among larvae. Consequently, their classification has changed over time and is still under discussion. In this study we focus on taxa of the Lucanus species in the western Palaearctic.

The genus Lucanus is subdivided into the subgenera Lucanus sensu stricto and Pseudolucanus Hope \& Westwood, 1845. Members of the latter have a peculiar stout body and substantial analogy of morphology that makes it quite easy to distinguish them from members of the subgenus Lucanus (Planet 1899). The male mandibles of Pseudolucanus are sickle shaped, their internal edge has a single denticle in most species (Lucanus has small denticles and one large denticle) and the apex is usually simple (Lucanus is mostly bifid) (Planet 1899, Baraud 1993). Furthermore, the integument of Pseudolucanus is relatively smooth with scattered and superficial punctuation whereas it is more stippled in Lucanus. Also, the sides of the pronotum of Pseudolucanus are strongly sinuate before the posterior angles (Baraud 1993). Previous studies (Didier and Séguy 1953, Benesh 1960, Krajcik 2001, Bartolozzi and Sprecher-Uebersax 2006, Hallan 2008, Fujita 2010) describe between four and seven species of Lucanus in western Palaearctic: i.e. L. (Lucanus) cervus (Linnaeus, 1758), L. (L.) ibericus Motschulsky, 1845, L. (L.) orientalis Kraatz, 1860, L. (L.) tetraodon Thunberg, 1806, Lucanus (Pseudolucanus) barbarossa Fabricius, 1801, L. (P.) busignyi Planet, 1909 and L. (P.) macrophyllus Kraatz, 1860.

The distribution of many of these taxa remains poorly resolved, however, we can consider some of them as endangered. The practice of removing old trees and dead wood in past and current forest management, has had detrimental effects on this group of saproxylic beetles (Jansson and Coskun 2008, Nieto and Alexander 2010). Con-
sequently, the loss of habitat might have reduced the range of some taxa, especially the Mediterranean taxa where deforestation started a few millennia ago (Jansson and Coskun 2008, Buse et al. 2010). At least L. c. cervus seems to be able to cope with urbanisation (Thomaes et al. 2008) as long as the habitat turnover allows recolonisation (Thomaes 2009). In addition, beetle collecting can be considered as a threat when it goes hand in hand with large scale habitat destruction or when species rarity causes overexploitation (Holden 2007, Tournant et al. 2012). Another possible consequence of the international stag beetle trade is the introduction of non-native specimens which may cause genetic introgression (Goka et al. 2004) and transmission of parasites potentially pathogenic to native stag beetles (cf. Goka et al. 2004, Kanzaki et al. 2011). Unfortunately, legal protection is often missing or inadequate. The widely distributed L. c. cervus is protected by the Habitats Directive of the European Union from 1992 (Luce 1996) and is listed as "near threatened" in the Red Data list of Europe (Nieto and Alexander 2010). Lucanus (P.) barbarossa and L. tetraodon are mentioned in the IUCN list, but are rated "of least concern" (IUCN 2012), while L. ibericus is considered to be "vulnerable" within the EU 27 (Nieto and Alexander 2010).

More detailed information on the distribution and ecology of this species group is needed to get a clear view on their conservation status. But unless the problem of identification of European and West Asian Lucanus is solved, it becomes difficult to set specific conservation priorities, without which rare, neglected and endangered species or Evolutionarily Significant Units (ESUs) may be unrecognised and thus, not given adequate conservation prioritisation (Ryder 1986, Waples 1991, Moritz 1994a, Moritz 1994b, Fraser and Bernatchez 2001). Molecular tools could help identification of stag beetles. The mitochondrial cytochrome $c$ oxidase subunit I (COI) is the most widely used gene in barcoding animals (Hebert et al. 2003). The barcoding practice entails the analysis of the DNA sequence of a part of this mitochondrial gene, typically between 600 and 900 bp . In this study, we investigated the use of the 3 ' end of the COI gene, different from the standard barcoding region, for the identification of western Palaearctic Lucanus species and subspecies.

## Material and methods

## Taxonomy and morphology

Lucanus cervus has the widest geographical distribution in the genus and is very variable in form, size and colour (Harvey et al. 2011). Many subdivisions (i.e. subspecies or morphotypes) have been proposed and discussed. Lucanus cervus cervus (Linnaeus, 1758), the main subspecies found throughout Europe, has, in general, four lamellae on the antennal clubs and is typically bicoloured (black head and thorax, and reddish brown elytra and mandibles). Lucanus cervus akbesianus Planet, 1896 with generally six lamellae and large mandibles with a very open apical fork, inhabits southern Turkey and Syria. Lucanus cervus turcicus Sturm, 1843 also has a six lamellate club, but its
mandibles are comparable to L. c. cervus. It is reported in Greece, Bulgaria and Trakya (European part of Turkey). Furthermore, L. c. judaicus Planet, 1902 with a four lamellate club and reddish brown colour, is found in the more eastern parts of Turkey and in northern Syria. Lucanus cervus laticornis Deyrolle, 1864, found in central and southern Turkey, has six long lamellae and the inner denticle of the mandibles is followed by two or three denticles. Lucanus cervus fabiani Mulsant \& Godart, 1855 is an endemic taxon inhabiting southern France and shows a five lamellate club and slender, slightly curved mandibles with a simple apex and post-median denticle along with a few other denticles. The taxa fabiani and pentaphyllus Reiche, 1853 are listed as synonyms of $L$. c. cervus by Bartolozzi and Sprecher-Uebersax (2006), but fabiani could well be considered as a valid species according to Boucher (unpublished data) while pentaphyllus may represent a small form of $L$. cervus with five lamellate clubs, a character that can also be found in L. c. cervus. Other taxa [tauricus Motschulsky, 1845 (described from Crimea), poujadei Planet, 1897 (Kurdistan), mediadonta Lacroix, 1978 (Georgia) and pontbrianti Mulsant, 1839 (France)], recognised by some authors as valid subspecies or simple synonyms, were not included in this study. Bartolozzi and Sprecher-Uebersax (2006) only list cervus and judaicus as separate subspecies. Hallan (2008) adds akbesianus, fabiani, mediadonta, tauricus and turcicus, while Krajcik (2001) further includes pontbrianti and laticornis, although Schenk and Fiedler (2011) perceived laticornis as a separate species. On the other hand, Didier and Séguy (1953) also list capreolus Fuessly, 1775 (considered a small form of L. cervus) and poujadei while Fujita (2010) only recognises poujadei but does not list tauricus and mediadonta or the [pentaphyllus + fabiani + pontbrianti] complex.

Lucanus ibericus can be found from Albania to Iran and is sometimes considered a synonym of $L$. orientalis. Unlike $L$. cervus, $L$. ibericus is entirely reddish brown, has a pronotum without a smooth discal line, but with a sinuate posterior and distinct toothed posterior angles (non-sinuate pronotum and blunt angles in L. cervus). The mandibles of the males, which are shorter than those of a typical male $L$. cervus of equal size, can have an apex with two equal teeth or with the inner tooth fainted and a large internal denticle in the middle. In addition, $L$. ibericus has six, rarely five, long lamellae on the antennal club.

Lucanus tetraodon described from France, Italy, North Africa, Albania and Greece, can be perceived as a central Mediterranean species. In contrast to $L$. cervus and $L$. ibericus, the basal denticle of the mandibles of $L$. tetraodon is placed in the lower half. Like $L$. ibericus, the pronotal sides have sharp posterior angles, but the pronotal disc misses the central smooth line. Lucanus tetraodon has six, occasionally five, lamellae on the antennal club. Lucanus tetraodon is by some authors subdivided in subspecies L. t. argeliensis Maes, 1995 in North Africa, L. t. provincialis Colas, 1949 in South France, L. t. corsicus Gautier des Cottes, 1860 in Corsica, L. t. sicilianus Planet, 1899 in Sicily and finally L. t. tetraodon Thunberg, 1806 elsewhere. In addition, specimens of problematic populations of $L$. cervus from a series of localities in central Italy (northern Latium and Umbria), are known to exhibit apparently intermediate morphological characters between L. cervus and $L$. tetraodon, which are sympatric in these areas (Santoro et al. 2009).

The Pseudolucanus species all have six long lamellae forming the antennal club, their body is stout and entirely reddish or blackish brown. Included in this study are $L$. (P.) barbarossa from the Iberian peninsula and the Maghreb, and L. (P.) macrophyllus reported in south-west Turkey. Krajcik (2001) and Hallan (2008) list the latter as a subspecies of $L$. ibericus. Schenk and Fiedler (2011) recently quoted populations of $L$. (P.) busignyi in western Turkey, but this taxon is not included in this study.

## Taxon sampling and DNA extraction

A large number of entomologists was contacted to obtain material from the different taxa and from different regions. The samples included whole beetles, especially in regions where identification is problematic, as well as parts of a beetle, sometimes found as road kill or as prey leftovers from birds. Samples were dried and kept at room temperature or preserved in absolute ethanol. In total 76 samples were collected. The species identification was performed, using comparative material and available identification keys. Six samples from Israel and Lebanon could not be identified to species. These unidentified Lucanus specimens have a shape resembling in general the medium to small males of $L$. c. akbesianus but with a mandibular structure similar to that of $L$. c. turcicus (Zilioli et al. unpublished data). The tissue samples used for DNA extraction depended on what was available, but were mostly legs, which contain large muscles and are therefore rich in mitochondrial DNA (mtDNA). DNA was extracted from ground samples with the E.Z.N.A. ${ }^{\ominus}$ Forensic DNA Kit (Omega Bio-Tek), except for samples K1 and U6 (Table 1) from which DNA was extracted following the salting out procedure described by Aljanabi and Martinez (1997). The integrity of the extracted DNA was checked spectrophotometrically on a ND-1000 Nano-Drop (NanoDrop Technologies) and its quality on $1 \%$ agarose gels.

## Sequencing

We first attempted to sequence the COI barcoding region with the primers developed by Folmer et al. (1994) on a subset of samples. Despite PCR optimization trials, amplification of this fragment largely failed. Instead, a 800 bp fragment of the 3 ' end of the COI gene was amplified using the primer set C1-J-2183 (5' CAACATTTATTTTGATTTTTTGG 3') and TL2-N-3014 (5' TCCAATGCACTAATCTGCCATATTA 3') (Simon et al. 1994). This fragment does not overlap with the standard barcoding region. For samples O9 and V44 (Table 1) we used species-specific primers (F - 5' GGGGCATCAGTAGACCTAGC 3' and R - 5' TTCAGCAGGTGGTATTAGTTGG 3'), designed from sequences on GenBank and used to PCR amplify a 1089 bp stretch of the COI gene. Reactions were performed in total volumes of $40 \mu \mathrm{l}$ containing $5.2 \mu \mathrm{l}$ of $10 \times$ Taq buffer with 500 mM KCl (Fermentas, Thermo Scientific), $3.12 \mu \mathrm{l}$ of $\mathrm{MgCl}_{2}(25 \mathrm{mM}), 0.78 \mu \mathrm{l}$ dNTP ( 10 mM ), $2.08 \mu \mathrm{l}$ of each

[^1]primer ( $10 \mu \mathrm{M}$ ), 0.8 U Taq DNA polymerase (Fermentas, Thermo Scientific), 26.42 $\mu \mathrm{l}$ sterile distilled water. $12 \mu \mathrm{l}$ of diluted DNA $(3.5-5 \mathrm{ng} / \mu \mathrm{l})$ was added. The temperature cycle was $94^{\circ} \mathrm{C}$ for 1 min , then 5 cycles of $94^{\circ} \mathrm{C}$ for $1 \mathrm{~min}, 45^{\circ} \mathrm{C}$ for 1 $\min 30 \mathrm{~s}$ and $72^{\circ} \mathrm{C}$ for 1 min and 30 s . This was followed by 40 cycles of $94^{\circ} \mathrm{C}$ for 1 $\mathrm{min}, 50^{\circ} \mathrm{C}$ for 1 min 30 s and $72^{\circ} \mathrm{C}$ for 1 min , and finally a single cycle at $72{ }^{\circ} \mathrm{C}$ for 5 min . PCR products were cleaned enzymatically with DNA Clean \& Concentrator $^{\mathrm{TM}}-5$ (Zymo Research). When samples failed to amplify, mostly dried or bad quality samples, internal primers were used to allow amplification of four overlapping fragments of about 250 bp within the same 3' end of the COI gene: LCint1 (F - 5' CTTCGGCCACCCAGAAGT 3' and $\mathrm{R}-5$ ' TCCAGTAGGAACAGCAATRAT 3'), LCint2 ( $\mathrm{F}-$ 5' $^{\prime} \mathrm{CGAGCCTACTTCACATCAGC} \mathrm{3'} \mathrm{and} \mathrm{R} \mathrm{-} \mathrm{5'} \mathrm{GCAAAAACT-}$ GCACCTATTGAAA 3'), LCint3 (F - 5' GCTCACTTCCATTATGTACTTTCAA 3' and R - 5' GAGAGCCAAATGATGAAATAATGTT 3') and LCint 4 ( $\mathrm{F}-$ 5' $^{\prime} \mathrm{CC}$ CTGATGCCTACACCACAT 3' and R - 5’ CCAATGCACTAATCTGCCATA 3’). PCR amplification was performed in $2.6 \mu \mathrm{l}$ of $10 \times$ Taq buffer with 500 mM KCl , $2.08 \mu \mathrm{l}$ of $\mathrm{MgCl} 2(25 \mathrm{mM}), 0.39 \mu \mathrm{ldNTP}(10 \mathrm{mM}), 2.6 \mu \mathrm{l}$ of each primer $(10 \mu \mathrm{M})$, 0.8 U Taq DNA polymerase (Fermentas, Thermo Scientific), $9.57 \mu \mathrm{l}$ sterile distilled water, resulting in a total volume of $20 \mu \mathrm{l}$ to which $6 \mu \mathrm{l}$ of diluted DNA (3.5-5 $\mathrm{ng} / \mu \mathrm{l}$ ) was added. The PCR reaction was then conducted with the following cycle: $94{ }^{\circ} \mathrm{C}$ for 3 min , then 45 cycles of $94^{\circ} \mathrm{C}$ for $45 \mathrm{~s}, 59^{\circ} \mathrm{C}$ for 45 s and $72{ }^{\circ} \mathrm{C}$ for 1 $\min 30 \mathrm{~s}$, and finally a single cycle at $72^{\circ} \mathrm{C}$ for 6 min . PCR products were checked on $2 \%$ agarose horizontal gels and purified using USB ${ }^{\circledR}$ ExoSAP-IT ${ }^{\ominus}$ (Isogen Life Science). DNA sequencing was performed by a commercial company (BaseClear, Leiden, the Netherlands) or on an automatic ABI 3500 Genetic Analyzer (Applied Biosystems). Both forward and reverse primers were used except when internal primers were used for PCR, in which case sequencing was performed using the respective forward primers (except for five samples of $L$. (P.) barbarossa, where both forward and reverse primers were used).

COI sequences available on GenBank were added. The COI sequence of L. c. cervus obtained by Lin et al. (2011; GenBank acc. no. FJ606555) was used as a reference for the subspecies with the highest number of specimens in this study. We selected two Asian stag beetle species, L. formosanus Planet, 1899 and L. hermani DeLisle, 1973, and Dorcus parallelipipedus (Linnaeus, 1758) (lesser stag beetle; Lucanidae) as outgroup species. Except for one available sample of the latter, the COI gene sequences of the taxa were obtained from GenBank (D. parallelipipedus: Hunt et al. 2007; GenBank acc. no. DQ156023; L. formosanus: Huang and Lin 2010; GenBank acc. no. FJ606632, FJ606630, FJ606628, FJ606626, FJ606624, FJ606622, FJ606583; L. hermani: Lin et al. 2011; GenBank acc. no.: FJ606552). In the study of Hunt et al. (2007) the Dorcinae formed a sisterclade of the Lucaninae. Finally, part of the COI sequence of L. tetraodon obtained by Hunt et al. (2007; GenBank acc. no. EF487727) was used in addition to the sequence of L. t. provincialis.

DNA sequences have been deposited in GenBank under accession numbers KF737071 to KF737133 (Table 1).

## Alignment and sequence quality control

Overall quality of the sequences was evaluated manually. Only samples with high quality chromatograms for at least 300 bp were retained for further analyses. Sequences were aligned by hand and using CLUSTALW v1.4 (Thompson et al. 1994) in BIOEDIT v7.0.0 (Hall 1999). Sequences were trimmed to 670 bases. Duplicate haplotypes were removed using DUPLICATESFINDER v1.1 (http://bioinfotutlets.blogs-pot.be/2009/09/duplicates-finder-java-standalone.html). We searched for potential NUMTs (nuclear mitochondrial pseudogene sequences) or heteroplasmy by manually checking for the presence of double peaks and indels, and by looking for stop codons (Song et al. 2008, Calvignac et al. 2011) using MEGA v 5.01 with the implemented invertebrate mtDNA genetic code to translate the sequences (Tamura et al. 2011). We only retained sequences with a maximum of 7 polymorphic positions, which were treated as ambiguities. Finally, we constructed a Neighbour-Joining (NJ) tree with MEGA v5.01 using 10,000 bootstraps, based on Kimura 2-parameter distances (K2P) (Kimura 1980). For comparison, a Bayesian inference approach (BI) was used as well. The Bayesian analysis was conducted with MRBAYES v3.1.2 (Huelsenbeck and Ronquist 2001, Ronquist and Huelsenbeck 2003) under the GTR+I+G model, simulating 4 Monte Carlo Markov Chains (MCMC) for 2,000,000 generations each. Trees were sampled every 100 generations and the first 300,000 generations were excluded as burn-in. A consensus tree was constructed with posterior probabilities. The MRBAYES analyses were carried out on the Bioportal at Oslo University (http://www.bioportal. uio.no). The GTR $+\mathrm{I}+\mathrm{G}$ model used in MRBAYES is closely related to the TIM3+I+G model, which was selected by JMODELTEST v0.1.1 (Guindon and Gascuel 2003, Posada 2008) as the best-fit model under the Akaike information criterion (AIC).

## Genetic distances and nucleotide diagnostics

As K2P-distance is the most commonly used distance metric in DNA barcoding (Hebert et al. 2003), it was employed here for comparison. It allows to compare the behavior of the DNA fragment we used to the standard barcode region which is situated in the same gene. When possible, simple nucleotide diagnostics were identified for each (sub)species. If less than two simple nucleotide diagnostics were present (Sarkar et al. 2002), a compound diagnostic was detected using the algorithm of Wong et al. (2009).

## Results

## Alignment and sequence quality

Of a total of 76 samples, thirteen samples with low quality sequences were removed: five L. c. cervus, one L. c. pentaphyllus, three L. c. turcicus and four L. (P.) barbarossa.

Three sequences showed a few double peaks: one $L$. (P.) barbarossa (SB6: 5 ambiguous sites), one $L$. (P.) macrophyllus (UB1: 7 ambiguous sites) and one unidentified species of Lucanus (J2: 2 ambiguous sites) (Table 1). None exhibited indels or stop codons which are indicative of the presence of NUMTs (Buhay 2009). The remaining 63 samples and 11 sequences obtained from GenBank are listed in Table 1. The final alignment entailed 74 sequences, representing 60 haplotypes. Incomplete sequences were obtained for the following taxa: taxon H 4 with 500 bp of which the reverse sequence failed and taxon J2 of which forward sequences of only the first and third smaller fragments could be produced, resulting in a total of 383 bp . Both taxa were specimens of the unidentified Lucanus specimens (Table 1). Likewise, the sequence of $L$. tetraodon found in GenBank (named X2), was 122 bp short at the 3' end. One other taxon, H3 (Lucanus sp.) missed a mere 5 bp at the 5 ' end.

Both the NJ tree and the BI tree showed the same overall configuration (Figure 1 and Appendix 1, respectively) except for the position of the unidentified Lucanus specimens. In the NJ tree these specimens fall into two clusters with unresolved affinities (Figure 1). In the BI tree they form a single well-supported clade together with specimens identified as L. c. judaicus and L. c. laticornis (Appendix 1). The unidentified specimens fail to form a single monophyletic cluster as one subclade also includes L. c. judaicus. The BI tree showed L. c. laticornis to be monophyletic with probability 1 , instead of paraphyletic as was shown in the NJ tree with bootstrap support below $70 \%$. In both trees, several species as well as subspecies fall into distinct clades, whereas L. c. cervus, L. c. turcicus, L. c. pentaphyllus, L. (P.) macrophyllus and L. ibericus cluster in the same shallow clade (called the ' $L$. c. cervus clade' hereafter). In addition, three out of four samples of L. c. pentaphyllus share a haplotype with L. c. cervus (haplotype A3) which is the most common haplotype among $L$. cervus sequences (Table 1). Within this clade L. c. cervus, L. c. turcicus and L. c. pentaphyllus are polyphyletic. Unexpectedly, one sample of $L$. (P.) barbarossa and the sample of $L$. (P.) macrophyllus are also embedded in this clade. Looking at the sequences, they only differ from haplotype A 3 at their five and seven ambiguous sites, respectively. Because the two other specimens of $L$. (P.) barbarossa form a separate clade with L. c. fabiani, sample SB6 is excluded from further calculations but will be discussed below.

## Genetic distances

The nucleotide composition of all the sequences was AT-rich, with $29.5 \% \mathrm{~A}, 35.2 \% \mathrm{~T}$, $15.5 \% \mathrm{G}$ and $19.7 \% \mathrm{C}$. There were $36.4 \%$ nucleotide sites variable and $12.1 \%$ variable amino acid sites, of which $94.3 \%$ and $77.8 \%$ were parsimony informative, respectively. When $D$. parallelipipedus was excluded from the dataset, variable sites decreased to $33.3 \%$ for nucleotides and $7.2 \%$ for amino acids ( $94.2 \%$ and $56.2 \%$ parsimony informative, respectively). Nucleotide composition and K2P-distances calculated for each codon position are shown in Table 3.

Although specimen J2 of the unidentified specimens of Lucanus clustered with the other specimens of the same taxon in the NJ and BI trees, the pairwise interspecific

Figure I. Bootstrap consensus NJ tree inferred from 10,000 replicates, with a cut off value of $70 \%$, based on K2P-distances between 60 haplotypes of the $3^{\prime}$ end of the COI gene.

K2P-distances with J2 differed substantially from those with H1 to H5 (comparisons with L. c. judaicus not included). More specifically, the minimum pairwise interspecific K2P-distance between J 2 and the other unidentified taxa was 0.064 opposed to $0.087-0.095$ when taking H1 to H5 into account. J2 is one of three incomplete sequences and missing information from position 179 to 399 in the sequence of J2 where several simple nucleotide diagnostics are present (Appendix 2). Therefore, this sample was removed from the dataset for subsequent analysis.

The congeneric interspecific K2P-distances between the western Palaearctic taxa and the eastern Asian species $L$. formosanus and $L$. hermani range from 0.156 to 0.198 . Distances between taxa of Lucanus and Dorcus went from 0.211 until 0.259. K2Pdistances within and between the investigated western Palaearctic taxa of Lucanus are shown in Table 2. As indicated by the NJ and BI trees, the taxa L. c. cervus, L. c. pentaphyllus, L. c. turcicus and L. (P.) macrophyllus cannot be distinguished based on the COI fragment; K2P-distances range from 0 to 0.021 , and all taxa are reciprocally polyphyletic. Whereas the first three subspecies of L. cervus are distinguished solely on the basis of the number of lamellae on the antennal club, $L$. (P.) macrophyllus is morphologically much more distinctive, resembling L. ibericus. Although $L$. ibericus is part of the L. c. cervus clade, it shows slightly higher K2P-distances with the other members of this clade ( $0.028-0.032$ ). Note that we only had a single specimen. Moderate to relatively high within (sub)species distances were found for L. c. laticornis (0.085), certain specimens of the unidentified Lucanus sp. (max. 0.054) and L. (P.) barbarossa (0.53). On the other hand, between the latter and L. c. fabiani a small to moderate distance exists ( 0.004 and 0.058 ). This is also the case between taxa H 2 and H 4 of the unknown Lucanus sp. and L. c. judaicus (K2P-distance of 0.018 and 0.016 , respectively). The remaining distances between (sub)species ranged from 0.087 and 0.179 .

These results do not show a distinct barcoding gap or other threshold to distinguish putative species, which is chiefly due to a lack of phylogenetic resolution to differentiate the said species and subspecies. If we consider the taxa of the L. c. cervus clade to be members of the same species, $99.4 \%$ of all intra(sub)specific comparisons showed K2P-distances below $5 \%$ and $99.8 \%$ of the pairwise inter(sub)specific distances were above 5\%. Nucleotide diagnostics are listed in Appendix 2. No diagnostic combination of nucleotide positions and characters were found for the taxa of the L. c. cervus clade, $L$. ibericus not included. As the number of species and the sample size per species are rather limited, the nucleotide diagnostics should be considered with caution.

## Discussion

The present study shows that the sequenced COI fragment could discriminate several of the investigated western Palaearctic Lucanus species and alleged subspecies of L. cervus. Well differentiated species and subspecies were L. c. akbesianus, L. c. laticornis and L. tetraodon, as well as the two eastern Asian species L. formosanus and L. hermani. Difficulties in molecular identification remained between L. c. fabiani and L. (P.) barba-
Table 2. Intra- and interspecific K2P-distances for the 670 bp COI gene of western Palaearctic Lucanus (sub)species. NA: intraspecific K2P-distance cannot be presented because only one sample is available.

rossa, L. c. judaicus and the unidentified Lucanus species, and between taxa of the L. c. cervus clade. Although thoroughly sampled within their distribution range, L. c. cervus and $L$. c. turcicus could not be discriminated with a barcoding approach. Likewise, three out of four samples of L. c. pentaphyllus possessed the most common haplotype of L. c. cervus. Next to introgression following recent or past hybridisation events, incomplete sorting of ancestral variation may be the reason for the polyphyletic pattern. It is not known if Lucanus can be infected with the endosymbiotic bacteria Wolbachia, which can cause mitochondrial introgression between closely related species (e.g. Whitworth et al. 2007). Nonetheless, infections with Wolbachia are quite common among insects, and should be taken into account (Hilgenboecker et al. 2008). However, the shift from four to five or even six lamellar segments on the antennal club is, at least in this tree of maternal inheritance, not synapomorphic among all individuals, and the number of lamellae may represent a case of parallel evolution or a phenotypically plastic trait within L. cervus, such that pentaphyllus and turcicus may merely represent morphotypes of $L$. cervus. This hypothesis seems less likely for $L$. (P.) macrophyllus. Although this taxon's haplotype only differed from the main L. c. cervus haplotype, A3, by its seven ambiguous sites, it has a very distinct morphology. The same can be said about $L$. ibericus, which was part of the same clade, but showed higher pairwise K2P-distances (0.028-0.032) when comparing it to the other taxa of the clade. Lumping $L$. ibericus and $L$. (P.) macrophyllus together with the $L$. cervus subspecies cervus, turcicus and pentaphyllus seems therefore ill advice.

Like L. (P.) macrophyllus, one sample of $L$. (P.) barbarossa, SB6, was embedded in the L. c. cervus clade, opposed to the other two samples that clustered with L. c. fabiani. The taxa of the latter group showed K2P-distances between 0.004 and 0.058 , which indicates a close relationship between L. c. fabiani and L. (P.) barbarossa, as well as $L$. (P.) barbarossa being very variable. High intraspecific variability could be indicative of cryptic diversity or population structure (Diptera: Meier et al. 2006; Lepidoptera, Lycaenidae: Wiemers and Fiedler 2007; Coleoptera, Nitidulidae: De Biase et al. 2012; Hemiptera, Cicadidae: Nunes et al. 2013). Despite the moderate to low genetic distance between $L$. (P.) barbarossa and L. c. fabiani, these taxa are morphologically very distinct. This leaves us with either incomplete lineage sorting or introgression. Considering that both taxa have very proximate distribution ranges, introgressive hybridisation is likely. Even complete loss of the original mitochondrial genome of a species,
resulting in a species with only mitochondrial genomes of the introgressed species is not unheard of (Hailer et al. 2012). Likewise, as L. c. cervus and L. (P.) barbarossa occur sympatrically in Spain and Portugal (Méndez 2003), recent hybridisation and introgression cannot be ruled out as another or supplementary cause of the polyphyletic status of L. (P.) barbarossa (Avise 2000). Because SB6 merely differed from A3 at its five ambiguous sites, it could be perceived as a shared haplotype, which would corroborate this hypothesis (e.g. Nicholls et al. 2012). Lucanus cervus akbesianus, L. c. laticornis and L. c. judaicus also have overlapping distributions. The former two were even sampled on the same tree in a Turkish forest (M. A. Cimaz, personal communication). In captivity, they do not seem to interbreed, which is concordant with our reporting of no shared haplotypes.

Finally, the Lucanus samples from Israel and Lebanon that were unidentified at the species level, seemed closely related and formed a paraphyletic clade with L. c. judaicus. Nevertheless, some of these samples could well be of a different species, indicated by the higher pairwise genetic distances (0.042-0.066). A detailed morphological and phylogenetic study is required here to investigate the number of species and relationship with L. c. judaicus.

A distinct barcoding gap was absent for several species and subspecies of Lucanus. This may either represent a low phylogenetic signal from the COI fragment for some relationships, a problem of basing a taxonomy on just one or a few morphological traits, or both. The use of the COI gene for barcoding purposes has had mixed results. High intraspecific variability (DeSalle et al. 2005) and closely related species (e.g. Funk and Omland 2003, Hajibabaei et al. 2006) can lead to an overlap in genetic distances, making the technique ineffective, as was shown here. In addition, NUMTs may complicate results and could cause the number of species to be overestimated (Song et al. 2008). Besides, the evolutionary history of the gene in question could be different from that of the studied species (Maddison 1997, Edwards 2009). Consequently, other or additional genes, ribosomal or nuclear, are recommended for barcoding purposes (Dupuis et al. 2012).

## Conclusions

This study revealed that while the 3 ' terminus of COI contained sufficient information to resolve relationships among a number of closely related taxa, many others could not be robustly discriminated. Genotyping of additional specimens, especially of $L$. (P.) macrophyllus, L. ibericus, L. c. judaicus, L. c. fabiani and L. c. laticornis, as well as all western Palaearctic taxa is needed to fully explore COI genetic diversity and to investigate the roles of phenotypic plasticity, hybridisation and incomplete lineage sorting underlying stag beetle biodiversity and inform taxonomic investigations. We therefore see this study as a starting point for future research which should also endeavour to combine analysis of nuclear markers, such as the internal transcribed spacer (ITS) and 28S rRNA gene (e.g. Smith et al. 2007), in combination with a detailed morphological investigation, to find a useful molecular identification tool for all western Palaearctic Lucanus sp.

## Authors' contributions

The work presented here was carried out in collaboration between all authors. AT, KDG, GA, PA and LB defined the subject and the design of the study. KDG designed methods and experiments in the laboratory and supervised laboratory work. KC analysed the data, interpreted results and wrote the paper. AT was responsible for collecting the samples and co-wrote the taxonomical part of the paper. JM discussed analyses. GA, ES, NMcK and PS provided five sequences and revised primarily the material and methods section and the interpretation of the results. MZ, LB and PA provided samples and co-wrote the paper, particularly the taxonomical section. DH and RM provided samples. All authors have contributed to, revised and approved the manuscript.

## Acknowledgements

We want to thank the following people for generously providing tissue samples of stag beetles or information: E. Atay, M. Avci, L. Barbiero, R. Bekchiev, G. Bonamie, S. Boucher, C. Bouget, H. Brustel, D. G. Carrilero, L.R. Castro, G. De Coninck, J. Ibero Caballero, A.M. Cimaz, I. de las Monjas, M. Fremlin, N. Gouix, C. Hawes, J-P. Huang, N. Jansson, A. Kairouz, S. Korneyev, V.A. Korneyev, D. Kovalchuk, I. López Pérez, Á. Martínez García, M. Méndez, M. Murat, L. Nádai, I. Nel, E. Orbach, H. Podskalská, S. Rastrero Sánchez, S. Reicher, O. Rittner, F. Roviralta Peña, P. Šípek, L. Valladares, J.T. Smit, Á. R. Quirós Menéndez. Also many thanks to Leen Verschaeve, Nancy Van Liefferinge, An Van Breusegem, David Halfmaerten and Sabrina Neyrinck (INBO) for laboratory assistance. We appreciate the constructive comments of three anonymous reviewers.
