10 **Abstract:** *Stethorus gilvifrons* Mulsant, native to the Mediterranean region, is often observed feeding on  
11 *Tetranychus turkestan* Ugarov & Nycolsky and *Eutetranychus orientalis* Klein on different host crops.  
12 Fecundity of *S. gilvifrons* on *T. turkestan* and *E. orientalis* was evaluated by placing newly emerged pairs  
13 on leaf discs infested with different developmental stages of *T. turkestan* or *E. orientalis*. They were  
14 maintained at 30°C and changed daily until death of the female. Adult female mean longevity was 58 d on  
15 *T. turkestan* and 45 d on *E. orientalis*. Mean fecundity was 175 eggs per female on *T. turkestan* and 318  
16 eggs per female on *E. orientalis*. No significant differences were detected in the duration of life stages  
17 between *T. turkestan* and *E. orientalis*. Mean preimaginal mortality was 20% on *T. turkestan* and 24%  
18 on *E. orientalis*, with no statistical differences. Mean generation time (T) was 21 and 23 days on *T.*  
19 *turkestan* and *E. orientalis*, respectively. Net reproductive rate ( $R_0$ ) was significantly greater on *E.*  
20 *orientalis* (94) than on *T. turkestan* (45), but the estimate of intrinsic rate of increase ( $r_m$ ) was not  
21 statistically different (0.193 and 0.179, respectively). Our results suggest that both *T. turkestan* and *E.*  
22 *orientalis* are essential prey for *S. gilvifrons* development and reproduction and that *E. orientalis* is  
23 slightly more suitable than *T. turkestan*.

24

25 **Key words:** *Stethorus gilvifrons*, developmental time, fecundity, life table, *Tetranychus turkestan*,  
26 *Eutetranychus orientalis*

27

## 28Introduction

29*Tetranychs turkestanii* Ugarov & Nycolsky and *Eutetranychus orientalis* Klein (Acari: Tetranychidae) are  
30two important pests in southwestern Iran agricultural systems. They cause significant damage to  
31horticultural plants in both the field and in greenhouses. The strawberry spider mite, *T. turkestanii*, is a  
32polyphagous cosmopolitan pest (Jeppson et al. 1975; Mossadegh and Kocheili 2003). It is one of the best  
33known pests in tropical ecosystems and it causes damage to cucurbitacean, leguminosae and other field  
34and horticultural plants (Jeppson et al. 1975; Kamali et al. 2004). The citrus spider mite, *E. orientalis*, is a  
35polyphagous species which is found in tropical regions that threatens many economically important  
36horticultural and ornamental plants (Jeppson et al. 1975; Kamali et al. 2004).

37Current control of these pests in Iran relies mainly on acaricides. Due to continuous use of pesticides,  
38these mite species have developed resistance to most available acaricides (Shishehbor, unpublished data).  
39In addition, public concern regarding pesticide residue in both food products and the environment  
40encouraged researchers to look for alternative methods of managing spider mites in field crops and fruit  
41trees. Therefore, there has been an increasing interest in controlling spider mites with biological control  
42agents (Roy et al. 2002; Roy et al. 2003; Gotoh et al. 2004).

43Different species of *Stethorus*, an acarophagous ladybug, including *S. loxtoni* Britton and Lee  
44(Richardson 1977), *S. madecassus* Chazeau (Gutierrez and Chazeau 1972; Chazeau 1974), *S. picipes*  
45Casey (Tanigushi and McMurtry 1977), *S. punctillum* Weise (Putman 1955; Skeroglu and Yigit 1992;  
46Roy et al. 2003), *S. japonicus* (Mori et al. 2005), *S. tridents* Gordon (Fiaboe et al. 2007) and *S. gilvifrons*  
47Mulsant ( Aksit et al. 2007; Taghizadeh et al. 2008a,b) have recently received intensive studies for their  
48effectiveness as predators on spider mites.

49*S. gilvifrons* is a native beneficial coccinellid in Iran (Mossadegh and Kocheili 2003) and other countries  
50in the region (McMurtry et al. 1970; Chazeau 1985; Aksit et al. 2007). It is common in fields of  
51sugarcane (Afshari 1998), date palm (Kajbaf Vala 1991, 1999) and castor bean (Modares Awal 2001) and  
52it is a good candidate for biological control of numerous spider mites (Chazeau 1985).

53As these two pests may be simultaneously present in horticultural plants, both in fields or greenhouses,  
54we evaluated the development and reproduction of *Stethorus gilvifrons* Mulsant feeding on both *T.*  
55*turkestanii* and *E. orientalis* as food sources. Although some bionomic studies of *S. gilvifrons* have been  
56conducted (Aksit et al. 2007; Matin 2008; Taghizadeh et al. 2008a, b), no detailed study has reported its

57biology on *T. turkestan*i and *E. orientalis*. The objective of this study is to quantify the effects of different  
58prey species on biological characteristics of *S. gilvifrons* which could lead to the development of a better  
59strategy for biological control of these two mite species using *S. gilvifrons*.

60

61

## 62Materials and methods

### 63Mites and coccinellid stock colonies

64.

65

66Our laboratory stock colonies of *Tetranychus turkestan*i, *Eutetranychus orientalis* and *Stetorus gilvifrons*  
67were established one month before starting the experiments with  $\approx 50$  adult individuals collected from  
68wild castor bean plants on the campus of the Shahid Chamran University, Ahvaz, Iran ( $31^{\circ} 20' N$ ,  $48^{\circ}$   
69 $40' W$ ). Two species of mites were reared separately on young castor plants (cultivar Ahvazy) which  
70were grown from seeds in plastic pots (20 cm diameter) in mesh covered wooden cages ( $60 \times 60 \times 120$   
71cm).

72Ladybird beetles were reared in two separate wooden cages (as described above) on a tritrophic system  
73(host plant castor bean; prey *T. turkestan*i and *E. orientalis*; predator *S. gilvifrons*). The wooden cages  
74were kept in the laboratory condition at  $20 \pm 1^{\circ} C$  and  $50 \pm 5\% R. H.$  The photoperiod was 14 L: 10 D,  
75using fluorescent lamps.

76Each culture was maintained by the addition of suitable castor bean seedlings at weekly intervals. Extra  
77plants were also grown to provide additional leaves for the Petri dish experiments. The experimental  
78arena consisted of 6.0 cm diameter cowpea and castor bean leaf discs (for *T. turkestan*i and *E. orientalis*,  
79respectively) placed upside down on a soaked foam base in individual 8.0 cm diameter Petri dishes. The  
80Petri dishes were covered with lids ventilated with a 0.12 mm mesh. A small paint brush was used to  
81transfer mites and coccinellids to the leaf discs in petri dishes. A stereomicroscope was used for  
82observations.

83

### 84Development and reproduction

85

86To obtain synchronized eggs, coccinellid females (ca. 20 for each mite species) were isolated for 24 hours  
 87on cowpea and castor bean leaf discs harbouring *T. turkestanii* or *E. orientalis*, respectively. Newly laid  
 88eggs of *S. gilvifrons* were then placed individually on respective leaf discs. Upon hatching, *S. gilvifrons*  
 89larvae were fed daily with excess (100) various stages of *T. turkestanii* and *E. orientalis*. The Petri dishes  
 90were placed in growth chamber ( $30 \pm 1$  °C, 60-70 % R. H. and 14: 10 L: D) and egg to adult  
 91developmental time and mortality of immature stages were recorded under each of the two different mite  
 92species. The presence of an exuvium was used as the criterion of a successful molting.

93Newly molted adult female coccinellid beetles (age <24 h old) reared from larva to adult on each of the  
 94two mite species were maintained individually on a leaf disc harbouring respective *T. turkestanii* or *E.*  
 95*orientalis* in a Petri dish with a young adult male (age <24 h old). Egg laying and mortality were recorded  
 96daily. Males that died or escaped from the experimental unit were replaced by the young ones (age <24 h  
 97old). Females that were trapped in the wet sponge or died because of improper handling were excluded  
 98from data analysis. At the onset of reproduction, females and males were transferred daily to fresh leaf  
 99discs and longevity (mean total adult life span) and fecundity (mean daily and total number of eggs laid  
 100per female) on the different mite species were recorded. All eggs were transferred to new leaf discs until  
 101adult eclosion and the numbers of male and female coccinellid beetles were recorded to determine the sex  
 102ratio.

### 103Data analysis

104Where appropriate, parameters such as development time, preoviposition time, oviposition time,  
 105postoviposition time, longevity and fecundity were subjected to either one- or two-way analysis of  
 106variance and mean separation by Fisher's protected LSD test ( $P < 0.05$ ) (SAS 2001). A series of Chi-  
 107square tests were conducted to determine if there were any significant differences in stage mortality for  
 108ladybirds reared on *T. turkestanii* or *E. orientalis*.

109Life and fecundity table parameters were estimated by combining data from the preimaginal development  
 110and adult survival and reproduction experiments on different prey species. The intrinsic rate of population  
 111increase was determined by interactive substitution of  $r_m$  values into the Lotka-Euler equation (Lotka,

1121924; Birch, 1948; Southwood, 1978) as follow:  $\sum e^{-r_m x} l_x m_x = 1$

113 where  $x$  is the mean age class,  $m_x$  is the mean number of female progeny per female of age  $x$ , and  $l_x$  is  
 114 probability of survival to age  $x$ . The sex ratio of 1 female:1 male was used to calculate life table  
 115 parameters. A trial number of values for  $r_m$  were substituted into the equation until the  $r_m$  value for which  
 116 the sum of the left side of the equation approximated unity. Net reproductive rate ( $R_o = \sum l_x m_x$ , the total  
 117 number of female offspring produced per female), mean generation time ( $T = \ln R_o / r_m$ ), doubling time  
 118 ( $DT = \ln 2 / r_m$ , number of days required for the population to double its number when the population reach  
 119 the stable age distribution), and finite rate of increase ( $\lambda = e^{r_m}$ , number of times the population will  
 120 multiply itself per unit of time) were also calculated (Chi and Su 2006).

121

## 122 Results

### 123 Development time of immatures

124 No statistical differences in developmental time of the immature stages of *S. gilvifrons* were found  
 125 between either prey species ( $df = 3, 47$ ;  $F = 1.42$ ;  $P = 0.2391$ ) or sex ( $df = 3, 42$ ;  $F = 2.53$ ;  $P = 0.1186$ ) (Table  
 126 1). No interaction was found between prey species and sex ( $df = 3, 47$ ;  $F = 0.99$ ;  $P = 0.3255$ ).

### 127 Mortality of Immatures

128 No statistical differences were observed in mortality of predator eggs, larvae and pupae between prey  
 129 species (Table 2). Mortality from egg to adult tended to be lower on *T. turkestanis* (20%) compared to *E.*  
 130 *orientalis* (24%), although the differences were not significant.

### 131 Sex ratio

132 Sex ratio of *S. gilvifrons* feeding on *T. turkestanis* and *E. orientalis* was 44.4 and 47.5% respectively,  
 133 which was not significantly different ( $df = 1, 8$ ;  $F = 2.46$ ;  $P = 0.1558$ ).

### 134 Reproductive parameters

135 Prey species had no significant effect on either preoviposition ( $df = 1, 34$ ;  $F = 0.000$ ;  $P = 1.00$ ) or  
 136 oviposition period ( $df = 1, 34$ ;  $F = 0.06$ ;  $P = 0.803$ ) (Table 3). However, postoviposition period was  
 137 significantly affected by prey species ( $df = 1, 34$ ;  $F = 29.62$ ;  $P = 0.0001$ ).

138 No statistical differences in male longevity of *S. gilvifrons* were found between prey species ( $df = 1, 13$ ;  
 139  $F = 0.02$ ;  $P = 0.888$ ) (Table 3). However, ANOVA indicated significant differences between female  
 140 longevity on two prey species ( $df = 1, 34$ ;  $F = 12.75$ ;  $P = 0.0011$ ).

141 Mean fecundity was 175.00 eggs per female on *T. turkestanii* and 316.00 eggs on *E. orientalis*, and mean  
142 oviposition rate (eggs/days) was 6.64 eggs on *T. turkestanii* and 10.94 eggs on *E. orientalis*. These  
143 differences were statistically significant ( $df= 1, 34; F= 20.24; P= 0.0001$  and  $df= 1, 34; F= 20.07; P=$   
144  $0.0001$ , respectively) (Table 3).

#### 145 Demographic parameters

146 Calculated daily intrinsic rate of natural increase ( $r_m$ ) of *S. gilvifrons* was 0.179 and 0.193 on *T. turkestanii*  
147 and *E. orientalis*, respectively (Table 4). Net reproductive rate ( $R_o$ ) was greater on *E. orientalis* (94.53)  
148 than on *T. turkestanii* (45.89), reflecting higher reproduction of *S. gilvifrons* on *E. orientalis* than on *T.*  
149 *turkestanii* (Figure 1).

#### 150 Discussion

151 Few differences between life history of *S. gilvifrons* feeding on *T. turkestanii* or *E. orientalis* were  
152 observed. Development time of female *S. gilvifrons* was approximately 10.00 days on both spider mites  
153 which is similar to the findings of Ahmad and Ahmad (1988) on the same prey species at the same  
154 temperature. However, longer developmental time of 12.53 days was reported by Hajizadeh (1995) on *T.*  
155 *urticae*, 12.01 by Aksit et al. (2007) on *T. cinnabarinus*, 11.03 by Matin (2008) on *O. afasiaticus* and  
156 12.49 days by Taghizadeh et al. (2008a) on *T. urticae* at the same temperature. The differences may be  
157 explained by disparities in prey-insect suitability of the tetranychid mites to *S. gilvifrons*, in addition to  
158 differences in the experimental conditions (photoperiod, relative humidity, and host plant species).

159 The egg to adult developmental time of males *S. gilvifrons* on both prey species was very close to the  
160 respective time of females. A similar trend has also been reported for *Stethorus picipes* Casey feeding on  
161 *Oligonychus punicae* (Tanigushi and McMurtry, 1977) and *Stethorus japonicus* Kamiya feeding on *T.*  
162 *urticae* (Mori et al., 2005).

163 In the only study available, Aksit et al. (2007) reported *S. gilvifrons* mortality at 39 and 65 % under short-  
164 day (8 h light) and long-day (16 h light) photoperiod, respectively, which is higher than our findings.

165 In our study, *S. gilvifrons* females longevity was at 58.0 and 45.05 days on *T. turkestanii* and *E. orientalis*,  
166 respectively. Similar results were also obtained on *O. afasiaticus* by Matin (2008) and on *T. atlanticus*  
167 by Georgis et al. (1974), but not by Aksit et al. (2007) and Taghizadeh et al. (2008b) who reported  
168 longevity of 8.29 and 11.40 days at 30 °C on *T. cinnabarinus* and *T. urticae*, respectively.

169According to our results the longevity of males on both prey species was longer than the respective time  
170of females. A similar trend has also been reported for *S. gilvifrons* feeding on *T. urticae* (Taghizadeh et al.,  
1712008b; Hajizadeh, 1995) and *Stethorus loi* Sasaji feeding on *Tetranychus kanzawai* Kishida (Shieh et al.,  
1721991). The reverse trend has been reported for *S. gilvifrons* feeding on *Oligonychus sacchari* (Afshari,  
1731998), *S. gilvifrons* feeding on *Oigonyshus afrasiaticus* (Matin, 2008), *Stethorus siphonulus* Kapur  
174feeding on *T. cinnabarinus* (Raros and Haramoto, 1974) and *Stethorus punctillum* feeding on  
175*Tetranychus viennensis* (Kasap and Aktug, 2003).

176In our study, total fecundity was 175.14 and 318.00 eggs per *S.gilvifrons* female on *T. turkestani* and *E.*  
177*orientalis*, respectively. These data are in line with the results of Matin (2008) and Taghizadeh et al.  
178(2008b), who reported 151.40 and 150.90 eggs for *S. gilvifrons* on *O. afrasiaticus* and *T. urticae*,  
179respectively. In contrast, Aksit et al (2007) reported only 28.60 eggs per female on *T. cinnabarinus*. We  
180can only attribute these differences to differing experimental conditions.

181Similar to our results, the sex ratio of *S. gilvifrons* feeding on *T. cinnabarinus* was reported to be around  
1821: 1 (Aksit et al. 2007).

183Other laboratory studies have reported a variety of  $r_m$  values for this coccinellid species: 0.152 (Aksit et  
184al. 2007) with *T. cinnabarinus* as prey, 0.189 (Matin, 2008) with *O. afrasiaticus* as prey and 0.191  
185(Taghizadeh et al. 2008b) with *T. urticae* as prey at 30 °C (Table 5).

186The intrinsic rate of increase ( $r_m$ ) for *S. gilvifrons* feeding on *E. orientalis* in this study (0.193) is higher  
187than previously reported values for this coccinellid beetle on other tetranychid species at the same  
188temperature. This reflects lower juvenile mortality, higher fecundity and longer adult life span of *S.*  
189*gilvifrons* when feeding on *E. orientalis*. Differences in the ecological factors viz. tetranychid prey  
190species, strain of coccinellid beetle, host plant as well as measurement methods may provide an  
191explanation for higher  $r_m$  value for *S. gilvifrons* on *E. orientalis* than on other tetranychid species.

192These results lend credence to reports that augmentative biological control of tetranychid mites with  
193*Stethorus* species can be effective in fruit trees and field crops (Obrycki and Kring 1998; Roy et al. 2003;  
194Fiaboe et al. 2007).
